Outline

- 1 Introduction
 - Phenology and climate change
 - The problem and our research
- 2 Methods
 - Mathematical model
 - Simulation scenarios
- 3 Results
 - Consumer – Resource interactions (only two species)
 - Trophic structure

Outline

- 2 Methods
 - Mathematical model
 - Simulation scenarios
- 3 Results
 - Consumer – Resource interactions (only two species)
 - Trophic structure

Phenology

- 1: a branch of science dealing with the relations between climate and periodic biological phenomena (as bird migration or plant flowering)
- 2: periodic biological phenomena that are correlated with climatic conditions

It is important because:

- Plays an important role at many scales (e.g. populations, communities) and processes (e.g. dispersal, growth, evolution)
- There is concern about the potential consequences of changes in species phenologies driven by global climate change

Effects of climate change

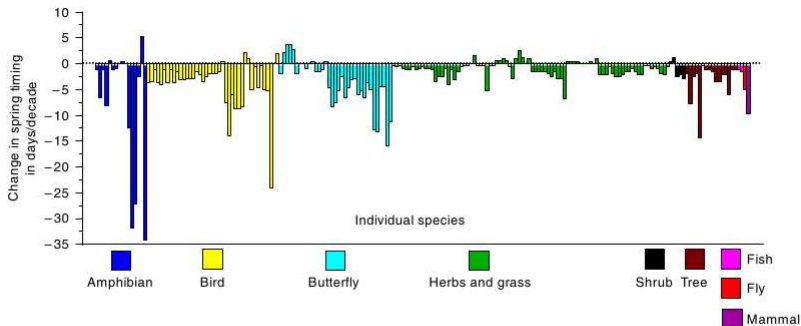

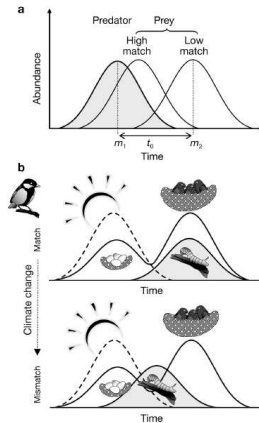

Fig. 2 Changes in timing of spring events in days decade⁻¹ for individual species grouped by taxonomy or functional type for the combined dataset. Each bar represents a separate, independent species. Negative values indicate advancement (earlier phenology through time) while positive values indicate delay (later phenology through time).

 - Trophic structure

Match–Mismatch Hypothesis

Goals

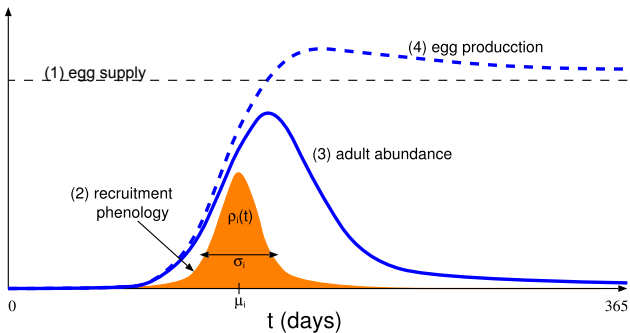

- Study the effects of changes of phenology on the abundances and dynamics of consumers and resources
 - Shifts in timing (when)
 - Changes of activity periods (how long)
- Study the consequences for top-down and bottom-up regulation, consumer–resource feedbacks
- Investigate the role of foodweb structure

Outline

- 1 Introduction
 - Phenology and climate change
 - The problem and our research
- 2 **Methods**
 - **Mathematical model**
 - Simulation scenarios
- 3 Results
 - Consumer – Resource interactions (only two species)
 - Trophic structure

This happens every year

Adults (blue line) emerge around day μ with an s.d. σ , from seeds or eggs produced by the adults in the previous year

Dynamics of interacting adults during one year

One resource (species 1) and its consumer (species 2)

$$\frac{dN_1}{dt} = \rho_1(t)n_1 - m_1 N_1 - a_{12} N_1 N_2$$
$$\frac{dN_2}{dt} = \rho_2(t)n_2 - m_2 N_2$$

- N_i biomass of adults
- $\rho_i(t)$ recruitment rate at day t
- n_i number of seeds or eggs
- m_i mortality or decay rate
- a_{ij} consumption rate of i by j

Seed/Egg production

During the same year

$$\frac{dB_1}{dt} = \frac{b_1 N_1}{1 + c_1 N_1} - d_1 B_1$$
$$\frac{dB_2}{dt} = e_2 a_{12} N_1 N_2 - d_2 B_2$$

B_i seeds or eggs

b_i, c_i resource growth rate and self-limitation coefficient

e_i consumer's conversion efficiency

d_i mortality or decay rate

Long-term dynamics

The long term dynamics, year after year, is given by

$$n_{1,\tau+1} = B_1(t = 365 | n_{1,\tau}, n_{2,\tau})$$
$$n_{2,\tau+1} = B_2(t = 365 | n_{1,\tau}, n_{2,\tau})$$

- 1 The number of seeds or eggs available for the next year ($\tau + 1$) is the net number produced at the end of the present year (τ)
- 2 All the adults left at the end of the present year die

Outline

 - Phenology and climate change
 - The problem and our research
- 2 **Methods**
 - Mathematical model
 - **Simulation scenarios**
- 3 Results
 - Consumer – Resource interactions (only two species)
 - Trophic structure

Phenological match/mismatch

We study the consequences of match/mismatch as follows

- 1 Set species 1 recruitment at $\mu_1 = 180$ (approx. mid year)
- 2 Set species 2 recruitment at $\mu_2 = \mu_1 + \Delta\mu$
amount of mismatch: $\Delta\mu = -100 : 5 : 100$ days
- 3 Follow the long term dynamics (seeds/eggs) for 100 to 300 years

- 3 Results
 - Consumer – Resource interactions (only two species)
 - Trophic structure

Trophic structure

We also consider three species in four *community modules*, i.e. consumer-resource arrangements

apparent competition

resource competition

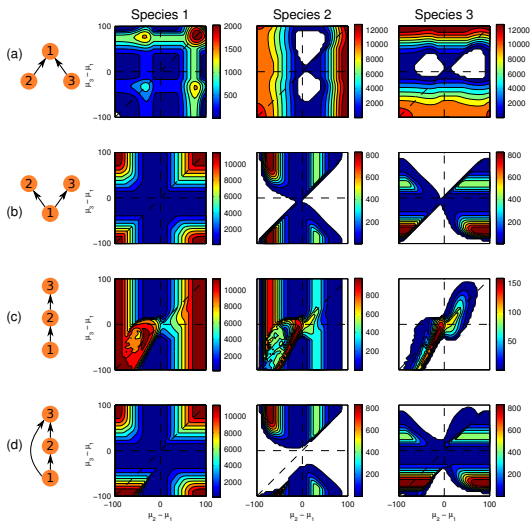

food chain

intraguild predation

Long-term abundances (seeds/eggs) and mismatch

Summary

- Consumers require temporal overlap with their resources. However, perfect matching also leads to overexploitation of resources
- Changes in the timing and the duration of the activity seasons can cause changes in long-term dynamics (stable equilibrium, cycles)
- In simple communities, the net effect of phenological mismatches is to some extent a superposition of their effects of on consumer-resource pairs
